

Vitto Full Stack Engineering Intern Assignment

Submission write-up | Nishu Kumari

What I built

I built a production-ready loan application portal with a responsive borrower intake form and an operations dashboard. The system supports strict client/server validation, UUID references, status filtering, debounced search, pagination, approval/rejection workflows, summary analytics, charts, CSV export, dark mode, reusable components, and mobile-first views. The Express API uses layered routes, controllers, services, validators, centralized error handling, parameterized PostgreSQL queries, and health checks.

Deployment choices

Frontend: Vercel for fast Vite deployments and SPA routing. **Backend:** Render Web Service for managed Node.js hosting.

Database: Neon PostgreSQL for a serverless, SSL-enabled production database. Secrets are stored only in platform environment variables; migration SQL and environment examples are included in the repository.

Known issues and improvements

Render's free instance may take a short time to wake after inactivity. The current application intentionally excludes authentication because it was not part of the assessment scope. With more time, I would add JWT-based role access, an immutable status audit log, automated API/UI tests, CI checks, server-side CSV export, and frontend route-level code splitting.
